Received 16 December 2005/Returned for modification 28 February 2006/Accepted 20 March 2006

Human coronavirus NL63 (HCoV-NL63), a recently discovered member of the Coronaviridae family, has spread worldwide and is associated with acute respiratory illness in young children and elderly and immunocompromised persons. Further analysis of HCoV-NL63 pathogenicity seems warranted, in particular because the virus uses the same cellular receptor as severe acute respiratory syndrome-associated coronavirus.

Coronavirus infection starts with the recognition of a specific receptor on the host cell surface by an S protein, followed by virus internalization, which occurs either immediately by direct fusion with the plasma membrane or after endocytosis. Fusion of the viral membrane with the cellular membrane triggers the release of the viral RNA genome into the host cell cytoplasm. Viral RNA is copied by the viral replicase in membrane-associated replication centers (14). During the replication process, copies of the full-length genomic RNA and a nested set of subgenomic mRNAs are generated. These subgenomic mRNAs are functional templates for the translation of the structural proteins encoded in the 3' one-third of the genome. Full-length viral RNA is encapsidated and released from the host cell as an infectious virus particle.

Human coronavirus NL63 (HCoV-NL63), a recently discovered (45, 55) member of the Coronaviridae family, has spread worldwide, is observed most frequently in the winter season, and is associated with acute respiratory illness and croup in young children, elderly people, and immunocompromised patients (2, 6, 15, 25, 29, 40, 53–56). A recent report suggested that HCoV-NL63 is the causative agent of Kawasaki disease (28), although other studies did not confirm this relationship (7, 26, 49). In the developed world, Kawasaki disease is the most common cause of acquired heart disease in children (37, 47). Further analysis of HCoV-NL63 pathogenicity seems warranted, in particular because the virus uses the same cellular receptor as severe acute respiratory syndrome-associated CoV (SARS-CoV) (34).

An effective antiviral treatment is required for HCoV-NL63-infected patients who are admitted to the intensive care unit due to acute respiratory disease. To investigate the therapeutic options, we tested several potential inhibitors that target specific steps of the coronavirus life cycle, e.g., receptor binding, membrane fusion, transcription, translation, posttranslational processing, and virus release. The compounds inhibiting the early phase of HCoV-NL63 infection appeared to be the most potent antivirals.

MATERIALS AND METHODS

Antiviral agents. Information about all 28 tested compounds is summarized in Table 1. The 50% inhibitory concentrations (IC50s, based on the cytopathic effect [CPE] reduction assay and viral yield) and 50% cytotoxic concentrations (CC50s, based on the MTS [3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium] inner salt assay) were determined for each antiviral agent. Human sera obtained from healthy adults were inactivated by incubation for 30 min at 56°C and stored at −80°C until use.

Plasmid construction, bacterial protein expression, and purification. For the production of the HR1 and HR2 peptides corresponding to amino acid residues 955 to 1064 (HR1) and 1241 to 1285 (HR2) of the HCoV-NL63 spike protein, a PCR fragment was prepared with the plasmid carrying the HCoV-NL63 spike gene (34). The primers 5’-CGGATCCCAAGCACGACTTAACTATG-3’ and 5’-CGGGATCCTGAGCGTTTCTGAGCCG-3’ were used for amplification.

5'-CGAATTCACAACTTCAAATCAACATATGT-3' and 5'-GGGATCCTTTAATTTAACATATCTT-3' were used for the amplification of HR1, and the primers 5'-GGGGATCCTTTAATTTAACATATCTT-3' and 5'-CGAATTCACAACTTCAAATCAACATATGT-3' were used for HR2. Bacterial expression and purification were then performed as described previously (12), with a few modifications. Lysosome (100 µg/mL), dithiothreitol (DTT; 7 mM), and surfosil (1%) were added to phenylmethylsulfonyl fluoride (PMSF; 1 mM) prior to sonication, and Triton X-100 (2.8%) was added to the supernatant after centrifugation, prior to glutathione–methylsulfonyl fluoride (GSH–MSF) purification. Production of the murine coronavirus (murine hepatitis virus [MHV] strain A59) HR2 peptide has been described previously (13).

Sepharose 4B purification. Production of the murine coronavirus (murine hepatitis virus [MHV] strain A59) HR2 peptide has been described previously (13).

Cell culture. LLC-MK2 cells were cultured in minimal essential medium (MEM; 2 parts Hanks' MEM and 1 part Earle's MEM) supplemented with 3% heat-inactivated fetal calf serum (PAA Laboratories), penicillin (100 U/mL), and streptomycin (100 µg/mL). Twenty-four hours prior to transfection, the cells were plated onto 96-well plates at a density of 2 x 10^4 cells/well in medium (100 µL per well) and cultured at 37°C with 5% CO2. Twenty-four hours prior to the addition of the drug, the cells were plated onto 96-well plates at a density of 4 x 10^5 cells/well in fresh medium (100 µL per well) with 100 µg of penicillin and 100 µg of streptomycin and cultured at 37°C with 5% CD2.

Cytopathic effect reduction assay. HCoV-NL63 (isolate Amsterdam 1) was obtained from a culture on LLC-MK2 cells as described previously (55). The infective titer of the virus was determined according to the Reed and Muench formula (46) on an LLC-MK2 cell monolayer. The virus stock has a titer of 2 x 10^3 50% tissue culture infectivity doses/ml. For the CPE reduction assay, cells were treated with serially diluted compounds and infected with HCoV-NL63 at a multiplicity of infection of 0.01. The CPE was scored visually at day 6 postinfection and confirmed with an MTS assay. Experiments were performed in quadruplicate.

Immunostaining-based HCoV-NL63 infection inhibition assay. Virus entry inhibition by the HR2 peptide was analyzed on LLC-MK2 cells in 96-well plates (4 x 10^4 cells per well). Cells were inoculated with HCoV-NL63 at a multiplicity of infection of 0.5 in the presence of serial dilutions of the peptides. The MHV HR2 peptide was included as a negative control. After incubation for 24 h, cells were washed with phosphate-buffered saline (PBS), fixed with 3% formaldehyde for 20 min, and permeabilized with 1% Triton X-100 in PBS for 5 min. After they were washed twice with PBS and blocked with PBS-5% fetal calf serum, the HCoV-NL63-positive cells were detected by intracellular peroxidase staining using a human polyclonal serum (1:200) in combination with a biotinylated anti-human antibody (1:250) and the VECTASTAIN ABC kit (Vector Laboratories). The reaction mixture was developed with 3-amin-9-ethylcarbazole (AEC; Sigma) according to the manufacturer's instructions. Experiments were performed in quadruplicate. Infected cells were counted using a light microscope.

Drug cytotoxicity. Cytotoxicity of the compounds was determined by measuring mitochondrial activity on day 6 posttreatment with MTS (CellTiter 96 ACeTone one solution cell proliferation assay; Promega) according to the manufacturer's instructions. Cytotoxicity measurements were confirmed by determining the mRNA levels of the housekeeping gene encoding glyceraldehyde-3-phosphate dehydrogenase (GAPDH). Experiments were performed in duplicate.

Transfection of LLC-MK2 cells with siRNA. Transfection with siRNA was performed with Lipofectamine 2000 (Invitrogen) according to the manufacturer’s protocol. siRNA-transfected cells were infected with HCoV-NL63 after 24 h.

Reverse transcription-PCR and real-time quantitative PCR. Total RNA was extracted from the medium and cells by the silica-affinity-based Boom extraction method (11) and eluted in 100 µl water. Reverse transcription was performed with Moloney murine leukemia virus reverse transcriptase (Invitrogen) (200 U per reaction) and 10 ng of random hexamers (Amersham Biosciences) in 10 mM Tris, pH 8.3, 50 mM KCl, 0.1% Triton X-100, 6 mM of MgCl2, and 50 µM of each deoxynucleoside triphosphate at 37°C for 90 min in a total volume of 40 µl. Viral RNA was used as a positive control. The CPE was scored visually at day 6 postinfection and confirmed with an MTS assay. Experiments were performed in quadruplicate. Infected cells were counted using a light microscope.

Transfection of LLC-MK2 cells with siRNA. Transfection with siRNA was performed with Lipofectamine 2000 (Invitrogen) according to the manufacturer’s protocol. siRNA-transfected cells were infected with HCoV-NL63 after 24 h.

for porcine epidemic diarrhea virus strain CV777 is AF353511. The sequence of the GAPDH gene (LLC-MK2 cells derived from Macaca mulatta) was deposited in GenBank under accession number DQ445913.

RESULTS

HCoV-NL63 inhibition assay. The inhibition of HCoV-NL63 infection can be determined using several assays. The most straightforward assay is based on the reduction of CPE. Six days after infection, HCoV-NL63-infected LLC-MK2 cells exhibit evident morphological changes consisting of cell enlargement, rounding, and, eventually, detachment from the surface (Fig. 1). Thus, infecting the target cells in the presence of serially diluted candidate antiviral agents provides a means of visualizing their inhibitory activity by scoring the reduction in CPE. LLC-MK2 cells seeded on the 96-well culture plate and subsequently infected with HCoV-NL63 in the presence of serially diluted compounds were scored for CPE using phase-contrast microscopy. Agents that showed antiviral activity in this initial assay were subsequently tested by measuring the virus yield at active concentrations of the compound.

Virus neutralization by purified human immunoglobulin G (IgG). Sera from virtually all healthy adults contain HCoV-NL63 antibodies (34). To determine the neutralizing potential of these antibodies, we tested 10 randomly selected human sera from healthy adults by the CPE reduction assay. All tested sera inhibited HCoV-NL63 infection at 25- to 50-fold dilutions, illustrating that the majority of adults carry neutralizing antibodies against HCoV-NL63.

To further explore the potential of neutralizing antibodies in antiviral therapy, we tested pooled purified human IgG from healthy donors (intravenous immunoglobulin [IVIG]). In fact, IVIG is part of the effective routine treatment for Kawasaki patients (43) and several immunodeficiency syndromes (23, 31). The CPE reduction assay demonstrates that this agent is very active against HCoV-NL63 infection (Fig. 2A). To confirm that CPE reduction is an accurate measurement of virus inhibition, the virus yield was determined for each serial IVIG dilution (Fig. 2B). The virus yield also allows a more precise measurement of the IC50 value, which was 200 μg/ml for IVIG. This concentration is ~10 times lower than the dose advised for treatment (2 g/kg of body weight) (43). The cell survival assay indicated that IVIG has a very low cytotoxicity (CC50 > 10 mg/ml), thus yielding a high selectivity index (CC50/IC50 > 50).

Inhibition of cell entry. The spike protein of HCoV-NL63 is a class I fusion glycoprotein consisting of a globular S1 domain that recognizes the receptor and a rodlike S2 domain involved in membrane fusion. After receptor binding and virus internalization, the S protein undergoes a structural switch, resulting in the exposure of the fusion peptide (13, 27). The HR1 and HR2 regions in the S2 domain rearrange and interact during the structural switch. Blocking this interaction between HR1 and HR2 provides an effective antiviral strategy (12, 13). The HCoV-NL63 spike protein contains HR1 and HR2 regions with a characteristic 7-residue periodicity. HR2 is located adjacent to the transmembrane domain, and HR1 is about 170 residues away, toward the N terminus. In all coronaviruses, HR1 is consistently larger than HR2, and all group 1 coronaviruses, including HCoV-NL63, show a remarkable insertion of two heptad repeats (14 amino acids) in both HR regions (13, 21).

Peptides corresponding to the HCoV-NL63 HR1 and HR2 regions were prepared with the bacterial glutathione S-transferase expression system and purified by using reverse-phase
high-performance liquid chromatography. It was previously shown for SARS-CoV and MHV (12, 13) that mixing HR1 and HR2 peptides leads to the assembly of an oligomeric complex that is resistant to 2% sodium dodecyl sulfate (SDS) (13). Using the same approach, we observed that the HR1 and HR2 peptides of the HCoV-NL63 spike protein behaved in a similar manner, forming an SDS-resistant oligomeric complex in an equimolar mixture (Fig. 3A).

The HR2 peptide was subsequently tested for its inhibitory potency in the CPE reduction assay. Concentration-dependent inhibition of HCoV-NL63 infection was observed with an IC₅₀ value of ~0.5 μM and a CC₅₀ value of >20 μM (Fig. 3B and C). This effect is sequence specific, because no inhibition was seen with a corresponding peptide derived from the HR2 region of MHV (MHV-HR2) that is known to block MHV infection (13) (Fig. 3D).

FIG. 2. Inhibition of HCoV-NL63 by IVIG. (A) CPE reduction mediated by IVIG. Filled circles indicate CPE development, empty circles indicate the absence of CPE, and the half-filled circle represents the development of CPE in 50% of wells. (B) Decrease in HCoV-NL63 virus yield after IVIG treatment and cell viability assay. Numbers on the y axis represent the percentages of produced virus and percentages of viable cells.

FIG. 3. Inhibition of HCoV-NL63 by the HR2 peptide. (A) SDS-polyacrylamide gel electrophoresis analysis of HR peptides separately and the HR1/HR2 complex formation. The molecular mass of the complex corresponds to the predicted heterohexamer. (B) CPE reduction mediated by HR2 peptide. Filled circles indicate CPE development, empty circles indicate the absence of CPE, and the half-filled circle represents the development of CPE in 50% of wells. (C) Decrease in HCoV-NL63 virus yield after HR2 treatment and cell viability assay. Numbers on the y axis represent the percentages of produced virus and percentages of viable cells. (D) Immunostaining-based HCoV-NL63 infection inhibition assay. Values on the y axis represent the percentages of infected cells.
Previous studies examined the antiviral activity of HR peptides (for coronaviruses) by immune peroxidase staining of infected cells after 24 h. Using this method, the IC50 was ~0.5 µM (Fig. 3D), identical to the value measured in the CPE reduction assay. NL63-HR2 exhibits the same powerful antiviral potency as the MHV-HR2 peptide against MHV infection (IC50 of 0.9 µM [13]). The activity of NL63-HR2 is much higher than the inhibiting activity described for the corresponding SARS-CoV HR2 peptide (IC50 of 17 µM [12]).

**Targeting the viral RNA by RNA interference.** siRNA-mediated degradation of the incoming full-length HCoV-NL63 genome will prevent transcription and, thus, virus production. We selected two siRNAs that target the S gene based on an algorithm for optimal siRNA design and the lack of complementarity with host gene sequences (Table 2). The siRNAs were designed against sequences that are conserved among HCoV-NL63 isolates, thus providing a broad antiviral activity. The target sequence is absent in other coronaviruses, as illustrated in Fig. 4, for the closest group 1 relatives, HCoV-229E and porcine epidemic diarrhea virus.

To examine the inhibitory capacity of HCoV-NL63-specific siRNA, we transfected cells with the synthetic siRNAs and subsequently infected them with HCoV-NL63. Transfection of siRNA1 and siRNA2 significantly inhibited the development of CPE, whereas transfection of the control siRNA3 did not (Fig. 5A). The latter result indicates that the transfection procedure does not interfere with CPE production and virus replication and that siRNA1 and siRNA2 inhibit HCoV-NL63 in a sequence-specific manner. The IC50 values are ~5 nM and -3 nM for siRNA1 and siRNA2, respectively (Fig. 5B). The CC50 values are higher than 200 nM. These results were confirmed by real-time reverse transcription-PCR analysis of the viral RNA load in the culture medium (Fig. 5C and D).

**Inhibition of HCoV-NL63 with nucleoside analogues.** A rational approach to the development of drugs for the treatment of HCoV-NL63 infection in patients is to identify compounds that specifically inhibit viral RNA replication. There are several possible mechanisms of action of nucleoside analogues: chain termination resulting from incorporation into elongated RNA strands, interference of these compounds with nucleotide synthesis, or inhibition of the viral polymerase. We tested two nucleoside analogues: β-d-N4-hydroxycytidine and 6-azauridine.

6-Azauridine is a uridine analogue with a histidine-like N-3 pKa (Fig. 6A). It is used as an antineoplastic antimetabolite as it interferes with pyrimidine biosynthesis, thereby preventing the formation of cellular nucleic acids. The antiviral effect of 6-azauridine has previously been documented for several virus types in vitro (19, 42), including coronaviruses (3, 18). This compound may thus act as a broad antiviral agent. We found that 6-azauridine is also an efficient inhibitor of HCoV-NL63 replication. The CPE reduction assay and viral yield determination indicate that the IC50 value is 35 nM (Fig. 6B and C). The CC50 value determined in the MTS assay is about 80 µM, a value consistent with previous reports (19). Thus, 6-azauridine exhibits a very high selectivity index for HCoV-NL63 inhibition.

The base-modified nucleoside analogue β-d-N4-hydroxycytidine (Fig. 7A) also inhibits HCoV-NL63 replication (Fig. 7B). The virus yield measurements indicate that the IC50 value is ~400 nM (Fig. 7C). The CC50 value determined in the MTS assay is about 80 µM.

**Agents with low inhibitory activity against HCoV-NL63.** Several other compounds were tested. We observed weak antiviral activity with ritonavir (16), the human immunodeficiency virus type 1 (HIV-1) protease inhibitor, at a concentration of >20 µM with a very low selectivity index (CC60 ~50 µM) (Table 3). Other HIV-1 protease inhibitors (nelfinavir, indinavir, amprenavir, or saquinavir) did not show any anti-HCoV-NL63 activity. We observed inhibition of HCoV-NL63 with aurantricarboxylic acid (32, 36), an RNase and polymerase inhibitor (22, 30), at a concentration of ~60 µM, but we could not exclude the possibility that the effect was the result of an increased pH of the medium (Table 3). We measured no anti-HCoV-NL63 activity in the following compounds: calpain inhibitors VI and III (4), glycyrrhizin (18), valinomycin (58), escin (58), ribavirin (41), dipryridamole (3), actinomycin D (38), and pentoxifylline (8). Several of these compounds have been reported to inhibit other coronaviruses.

**DISCUSSION**

The CPE reduction assay of HCoV-NL63-infected LLC-MK2 cells provides an easy and reproducible method for the evaluation of candidate antiviral compounds. We selected antiviral compounds that potentially target different stages of the HCoV-NL63 life cycle. Of the 28 compounds tested, we identified 6 compounds that effectively inhibit HCoV-NL63 replication. These compounds interfere at an early stage of virus replication: receptor binding, virus-cell membrane fusion, cytoplasmic stability of viral RNA, and transcription (Table 2).

All of the serum samples tested for the presence of neutral-
FIG. 5. Inhibition of HCoV-NL63 with two specific siRNAs. (A) LLC-MK2 cells transfected with 25 nM siRNA1 and siRNA2 and 50 nM siRNA3 and infected with HCoV-NL63. CPE was observed only in the culture transfected with control siRNA3. The images were taken 6 days postinfection. (B) CPE reduction mediated by siRNA1 and siRNA2. Filled circles indicate CPE development, and empty circles indicate the absence of CPE. (C) Decrease in HCoV-NL63 virus yield after siRNA1 treatment and cell viability assay. Numbers on the y axis represent the percentages of produced virus and percentages of viable cells. (D) Decrease in HCoV-NL63 virus yield after siRNA2 treatment and cell viability assay. Numbers on the y axis represent the percentages of produced virus and percentages of viable cells.
izing antibodies against HCoV-NL63 were positive. Thus, it is not surprising that we also measured potent inhibition with IVIG, which is consistent for 95% of pooled human IgGs isolated from the sera of healthy donors. IVIG is approved as an intravenously delivered drug by the Food and Drug Administration and is successfully used to treat several diseases, mostly primary immune deficiencies and autoimmune neuromuscular disorders but also respiratory diseases (e.g., respiratory syncytial virus) (33) and Kawasaki disease (50). The effectiveness of IVIG therapy for Kawasaki disease supports the recent claim that HCoV-NL63 is the causative agent of this disease (28), although it does not provide independent evidence for such a correlation, especially because there is accumulating evidence against such an association (7, 26, 49). IVIG treatment may be applied to severe HCoV-NL63-related diseases, as the in vitro inhibitory concentration is about 10 times lower than the therapeutic dose advised for treatment.

The spike proteins of coronaviruses are class I fusion proteins that exhibit a characteristic membrane fusion mechanism that is driven by conformational changes in the spike protein. The association of the HR1 and HR2 domains brings the fusion peptide that is located near the N terminus of HR1 in close proximity to the transmembrane domain, thereby facilitating membrane fusion. Peptides corresponding to the HR1 and HR2 domains were found to associate tightly with the prefusion complex, thus blocking the conformational switch, as has been observed previously for retrovirus and paramyxovirus

¹ With >50% of cells viable. ² ND, not determined.
fusion proteins (10, 24). An NL63-HR2 peptide was able to inhibit HCoV-NL63 infection of LLC-MK2 cells in a concentration-dependent manner. The effect is supposedly mediated by the competitive binding of NL63-HR2 to the HR1 region of the HCoV-NL63 spike protein, thus blocking the conformational switch and, consequently, the close apposition of the fusion peptide and transmembrane domain and, hence, membrane fusion. The NL63-HR2 peptide shows an antiviral potency against HCoV-NL63 similar to that of an MHV-directed HR2 peptide against MHV (13) but is more potent than the SARS-HR2 peptide (12) (IC_{50} values of 0.5, 0.9, and 17.0 μM, respectively). We present the first report that HR regions present in the S protein of group 1 coronaviruses, which typically contain a 14-amino-acid insert compared to group 2 coronaviruses, associate into complexes and function similarly to group 2 HR peptides (12, 13). The success of the antiviral T20 peptide against HIV-1 demonstrates the clinical potential of this class of new antivirals.

Following fusion with the host cellular membrane, viral RNA is released into the cytoplasm of the host cell. We found that targeting HCoV-NL63 RNA by employing the RNA interference machinery and transfection of cells with two siRNAs specific for HCoV-NL63 resulted in a profound inhibition of viral replication. The targeted RNA encodes the S glycoprotein, which initiates entry of the virus into susceptible cells; entry is mediated by binding to the cellular receptor, which leads to membrane fusion. The choice of the S gene as a target was also based on the theoretical sequence requirements for an effective siRNA. To avoid the possibility that sequence variation among different HCoV-NL63 strains might restrict the inhibitory effect, we chose well-conserved target sequences in the S gene. The effectiveness of siRNA against respiratory tract diseases in a therapeutic setting was demonstrated recently by the intranasal administration of siRNA targeting respiratory syncytial virus, parainfluenzavirus, and SARS-CoV, with or without transfection reagents, in mouse and monkey models (9, 39, 59). Inhaled siRNA in low doses may offer a fast, potent, and easily administered antiviral tool against HCoV-NL63 infection in humans.

The HCoV-NL63 positive-strand RNA is copied by the viral-RNA-dependent RNA polymerase via a negative-strand intermediate. We tested two pyrimidine nucleoside analogues that could potentially interfere with transcription: β-D-2′-N4-hydroxycytidine and 6-azauridine. Nucleoside analogues may be incorporated in the new nascent strand during transcription and cause chain termination. Several pyrimidine ribonucleoside analogues, including 6-azauridine (44, 57), act as antimetabolites, exerting pharmacological effects in their monophosphate forms by inhibiting UMP synthase (17) and thereby interfering with UTP metabolism. Additionally, incorporation of the nucleoside analogues may change the processivity and fidelity of transcription. This change results in an increased mutagenicity rate that forces the replicon into “error catastrophe,” as described previously for ribavirin (1, 20). Nucleoside analogues are known for their inhibition of several types of viruses, including HIV, pestivirus, hepatitis C virus, flavivirus, hepatitis A virus, West Nile virus, feline infectious peritonitis virus, and SARS-CoV (4, 5, 35, 42, 48, 51, 52). Both compounds show very potent antiviral activities, with IC_{50} values of 35 and 400 nM for β-D-2′-N4-hydroxycytidine and 6-azauridine, respectively. Relatively high cytotoxicity is compensated for by low IC_{50} values and thus a high selectivity index.

Recent data indicate that HCoV-NL63 is the most prevalent human coronavirus that is associated with acute respiratory diseases, group, and possibly Kawasaki disease in children. The lack of an effective vaccine or drug motivated us to design and evaluate therapeutic agents that could inhibit viral replication and thus provide a potential therapy for treating acute respiratory illness of children and immunocompromised patients. Combined with fast diagnostic tools to recognize HCoV-NL63 infection, these antivirals may provide a more appropriate therapy than the routine treatments with steroids, adrenaline, and antibiotics. The agents described in this report may be used in a mono- or multidrug therapy setting, thereby inhibiting viral infection at different stages of the replication cycle.
