We report that GRL-0519, a novel nonpeptidic human immunodeficiency virus type 1 (HIV-1) protease inhibitor (PI) containing tris-tetrahydrofuranylurethane (tris-THF) and a sulfonamide isostere, is highly potent against laboratory HIV-1 strains and primary clinical isolates (50% effective concentration [EC$_{50}$], 0.0003 to 0.0007 μM) with minimal cytotoxicity (50% cytotoxic concentration [CC$_{50}$], 44.6 μM). GRL-0519 blocked the infectivity and replication of HIV-1$_{314A}$-3 variants selected by up to a 5 μM concentration of ritonavir, lopinavir, or atazanavir (EC$_{50}$, 0.0028 to 0.0033 μM). GRL-0519 was also potent against multi-PI-resistant clinical HIV-1 variants isolated from patients who no longer responded to existing antiviral regimens after long-term antiretroviral therapy, highly darunavir (DRV)-resistant variants, and HIV-2RD. The development of resistance against GRL-0519 was substantially delayed compared to other PIs, including amprenavir (APV) and DRV. The effects of nonspecific binding of human serum proteins on GRL-0519's antiviral activity were insignificant. Our analysis of the crystal structures of GRL-0519 (3OK9) and DRV (2IEN) with protease suggested that the tris-THF moiety, compared to the bis-THF moiety present in DRV, has greater water-mediated polar interactions with key active-site residues of protease and that the tris-THF moiety and parame-thoxy group effectively fill the S2 and S2' binding pockets, respectively, of the protease. The present data demonstrate that GRL-0519 has highly favorable features as a potential therapeutic agent for treating patients infected with wild-type and/or multi-PI-resistant variants and that the tris-THF moiety is critical for strong binding of GRL-0519 to the HIV protease substrate binding site and appears to be responsible for its favorable antiretroviral characteristics.
strains and primary clinical isolates, including multi-PI-resistant variants with minimal cytotoxicity. In addition, GRL-0519 was active against HIV-2\textsubscript{ROD} as well as HIV-1 isolates examined. We also selected HIV-1 variants with GRL-0519 by propagating a laboratory wild-type HIV-1\textsubscript{NL4-3} in MT-4 cells in the presence of increasing concentrations of GRL-0519 and determined the amino acid substitutions that emerged under the pressure of GRL-0519 in the protease-encoding region. In addition, we evaluated the effects of nonspecific binding of physiological human serum proteins on GRL-0519’s anti-HIV-1 activity. We further analyzed the previously published crystal structure of GRL-0519 with protease (Protein Data Bank [PDB] ID, 3OK9) to gain a better understanding of the present antiviral data. The crystal structure analyses indicated that GRL-0519 has strong polar interactions with key residues in the active site of the protease. GRL-0519 also has several water-mediated polar interactions and tight van der Waals interactions with protease residues, suggesting that GRL-0519 binds very tightly in the active site of the protease.

**MATERIALS AND METHODS**

**Cells and viruses.** MT-2 and MT-4 cells were grown in RPMI 1640-based culture medium supplemented with 10% fetal calf serum (FCS) (JRH Biosciences, Lenexa, MD), 50 units/ml penicillin, and 100 µg/ml kanamycin. The following HIV strains were employed for the drug susceptibility assay (see below): HIV-1\textsubscript{NL4-3}, HIV-1\textsubscript{IIIB}, HIV-2\textsubscript{ROD}, HIV-1\textsubscript{ERS104pre} (18), clinical HIV-1 strains isolated from drug-naive patients with AIDS, and six HIV-1 clinical strains that were originally isolated from patients with AIDS who had received 9 to 11 anti-HIV-1 drugs over the past 32 to 83 months and that were genotypically and phenotypically characterized as multi-PI-resistant HIV-1 variants (19, 20). All primary HIV-1 strains were passaged once or twice in 3-day-old phytohemagglutinin-activated peripheral blood mononuclear cells (PHA-PBM), and the virus-containing culture supernatants were stored at −80°C until they were used as sources of infectious virions.

**Antiviral agents and human serum proteins.** Roche Products Ltd. (Welwyn Garden City, United Kingdom) and Abbott Laboratories (Abbott Park, IL) kindly provided saquinavir (SQV) and ritonavir (RTV), respectively. Amprenavir (APV) was a courtesy gift from GlaxoSmithKline, Research Triangle Park, NC. Lopinavir (LPV) was kindly provided by Japan Energy Inc., Tokyo, Japan. Atazanavir (ATV) was a contribution from Bristol Myers Squibb (New York, NY). Darunavir (DRV) was synthesized as previously described (21). Human serum albumin (HSA) and α1-acid glycoprotein (AAG) were purchased from Sigma-Aldrich (St. Louis, MO).

**Drug susceptibility assay.** The susceptibility of HIV-1\textsubscript{LAI} or HIV-2\textsubscript{ROD} to various drugs was determined as previously described with minor modifications. Briefly, MT-2 cells (10\textsuperscript{6}/ml) were exposed to 100 50% tissue culture infectious doses (TCID\textsubscript{50}) of HIV-1\textsubscript{LAI} or HIV-2\textsubscript{ROD}, in the presence or absence of various concentrations of drugs in 96-well microculture plates and incubated at 37°C for 7 days. After incubation, 100 µl of the medium was removed from each well and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) solution (10 µl, 7.5 mg/ml in phosphate-buffered saline) was added to each well in the plate, followed by incubation at 37°C for 2 h. After incubation to dissolve the formazan crystals, 100 µl of acidified isopropanol containing 4% (vol/vol) Triton X-100 was added to each well, and the optical density was measured in a kinetic microplate reader (Vmax; Molecular Devices, Sunnyvale, CA). All assays were performed in duplicate or triplicate. In some experiments, MT-2 cells were chosen as target cells in the MTT assay, since these cells undergo greater HIV-1-elicited cytopathic effects than MT-4 cells. To determine the sensitivity of primary HIV-1 isolates to drugs, PHA-PBM (10\textsuperscript{5}/ml) were exposed to 50 TCID\textsubscript{50} of each primary HIV-1 isolate and cultured in the presence or absence of various concentrations of drugs in 10-fold serial dilutions in 96-well microculture plates. In determining the drug susceptibilities of certain laboratory HIV-1 strains, MT-4 cells were employed as target cells as previously described, with minor modifications. In brief, MT-4 cells (10\textsuperscript{5}/ml) were exposed to 100 TCID\textsubscript{50} of drug-resistant HIV-1 strains in the presence or absence of various concentrations of drugs and cultured at 37°C. On day 7 of culture, the supernatants were harvested and the amounts of p24 (capsid [CA]) Gag protein were determined by using a fully automated chemiluminescent enzyme immunoassay system (Lumipulse F; Fujirebio Inc., Tokyo, Japan) (22, 23). Drug concentrations that suppressed the production of p24 Gag protein by 50% (50% effective concentration [EC\textsubscript{50}]) were determined by comparison with the p24 production level in a drug-free control cell culture. All assays were performed in duplicate or triplicate. PHA-PBM were derived from a single donor in each independent experiment. Thus, to obtain the data,
three different healthy donors were recruited. For determining the anti-retroviral activity and cytotoxicity of a drug, we used the same cells and cultured them for the same 7 days. The MTI assay was employed for HIV-1LAI and HIV-2ROD, while the p24 assay was employed for clinical HIV-1 isolates and drug-resistant HIV-1 strains.

Creation of PI-resistant HIV-1 variants in vitro. MT-4 cells (10^4/ml) were exposed to HIV-1NL4-3 (500 TCID_50) and cultured in the presence of various PIs at an initial concentration equal to its EC50. Viral replication was monitored by the determination of the amount of p24 Gag produced by MT-4 cells. The culture supernatants were harvested on day 7 and were used to infect fresh MT-4 cells for the next round of culture in the presence of increasing concentrations of each drug. When the virus began to propagate in the presence of the drug, the drug concentration was increased generally 2- to 3-fold. Proximal DNA samples obtained from the lysates of infected cells were subjected to nucleotide sequencing. This drug selection procedure was carried out until the drug concentration reached 5 μM, as previously described (24–26).

In the experiments for selecting drug-resistant variants, MT-4 cells were also exploited as target cells, since HIV-1 in general replicates at higher levels in MT-4 cells than in MT-2 cells, as described above.

Determination of nucleotide sequences. Molecular cloning and determination of the nucleotide sequences of HIV-1 strains passaged in the presence of anti-HIV-1 agents were performed as previously described (24). In brief, high-molecular-weight DNA was extracted from HIV-1-infected MT-4 cells by using the InstaGene Matrix (Bio-Rad Laboratories, Hercules, CA) and was subjected to molecular cloning, followed by sequence determination. The primers used for the first round of PCR with the entire Gag- and protease-encoding regions of the HIV-1 genome were LTR F1 (5'-GAT GCT ACA TAT AAG CAG CTG C-3') and PR12 (5'-CTC GTG ACA AAT TTC TAC TAA TGC-3'). The first-round PCR mixture consisted of 1 μl of proviral DNA solution, 10 μl of Premix Taq (Ex Taq version; Takara Bio Inc., Otsu, Japan), and 10 pmol of each of the first PCR primers in a total volume of 20 μl. The PCR conditions used were an initial 3 min at 95°C, followed by 35 cycles of 40 s at 95°C, 20 s at 55°C, and 2 min at 72°C, with a final 10 min of extension at 72°C. The first-round PCR products (1 μl) were used directly in the second round of PCR with primers LTR F2 (5'-GAG ACT CTG GTA ACT AGA GAT C-3') and KSMA2.1 (5'-CCA TCC CGG GGT TTA ATT TTA CTG G-TCA-3') under the following PCR conditions: an initial 3 min at 95°C, followed by 35 cycles of 30 s at 95°C, 20 s at 55°C, and 2 min at 72°C, with a final 10 min of extension at 72°C (a stick diagram of HIV-1 genome PCR amplification for sequence analysis is shown in Fig. S1 in the supplemental material). The second-round PCR products were purified with spin columns (MicroSpin S-400 HR columns; Amersham Biosciences Corp., Piscataway, NJ), cloned directly, and subjected to sequencing with a model 3130 automated DNA sequencer (Applied Biosystems, Foster City, CA).

Determination of replication kinetics of GRL-0519-resistant HIV-1NL4-3 variants and wild-type HIV-1NL4-3. The GRL-0519-resistant variant at passage 37 was propagated in fresh MT-4 cells without GRL-0519 for 7 days, and aliquoted HIV-1NL4-3 virion stocks were stored at -80°C until use. MT-4 cells (3.2 × 10^5) were exposed to the HIV-1NL4-3(GR) or wild-type HIV-1NL4-3 Preparation containing 10 ng/ml p24 in 6-well culture plates for 3 h, and the newly infected MT-4 cells were washed with fresh medium and divided into 4 fractions, each cultured with or without GRL-0519 (final concentration of MT-4 cells, 10^4/ml; drug concentrations, 0, 0.005, 0.01, and 0.015 μM). The amounts of p24 were measured every 2 days for up to 7 days.

Generation of recombinant HIV-1 clones. To generate HIV-1 clones carrying the desired amino acid substitutions, site-directed mutagenesis was performed with a QuickChange site-directed mutagenesis kit (Stratagene, La Jolla, CA), and the amino acid substitution-containing genomic fragments were introduced into pHIV-1NL4-3Smp. Determination of the nucleotide sequences of the plasmids confirmed that each clone had the desired amino acid substitution but no unintended amino acid substitutions. Each recombinant plasmid was transfected into COS7 cells with

Lipofectamine LTX transfection reagent (Invitrogen, Carlsbad, CA), and the infectious virions thus made were harvested for 72 h after transfection and stored at ~80°C until use.

Structural analysis of interactions of GRL-0519 and DRV with protease. The crystal structures of HIV-1 protease complexed with GRL-0519 or DRV were obtained from the protein data bank (PDB ID, 3O9K and 2IEN, respectively). The inhibitor conformation with the higher occupancy in the crystal structure was considered for analysis. Bond orders were properly assigned to the inhibitor molecules. Hydrogens were added to all the heavy atoms, and their positions were optimized in an OPLS2005 force field (27) with constraints on heavy atom positions. A cutoff distance of 3.0 Å between a polar hydrogen and oxygen or nitrogen was used to determine the presence of hydrogen bonds. The structures were analyzed using Maestro version 9.3 (Schrodinger, LLC, New York, NY, 2012).

RESULTS

Antiviral activities of GRL-0519 and -0529 against HIV-1LAI and HIV-2ROD and their cytotoxicities. We first examined the antiviral potencies of GRL-0519 and -0529 against a variety of HIV-1 isolates. GRL-0529 showed only moderate anti-HIV-1 activity against a laboratory wild-type HIV-1 strain, HIV-1LAI, and an HIV-2 strain, HIV-2ROD, with EC50s of 0.33 and 0.40 μM, respectively (Table 1). Conversely, GRL-0519 was extremely potent against HIV-1LAI with an EC50 of 0.0007 μM compared to other clinically available Food and Drug Administration (FDA)-approved PIs examined, including DRV (Table 1), as assessed with the MTT assay using MT-2 target cells, while its cytotoxicity was evident only at high concentrations (50% cytotoxic concentration [CC50], 44.6 μM) and the selectivity index proved to be highly favorable at 63,714 (Table 1). GRL-0519 was also very potent against HIV-2ROD with an EC50 of 0.0004 μM (Table 1).

GRL-0519 is potent against various PI-selected laboratory HIV-1 variants. We also examined GRL-0519 against an array of HIV-1NL4-3 variants, which had been selected by propagating HIV-1NL4-3 in the presence of increasing concentrations (up to 5 μM) of each of 4 FDA-approved PIs (RTV, APV, ATV, and LPV) in MT-4 cells (24). Such variants had acquired various PI resistance-associated amino acid substitutions in the protease-encoding region of the viral genome (Table 2, note a). Each variant was highly resistant to the PI by which the variant was selected and showed significant resistance, with an EC50 of >1 μM. GRL-0519 was highly active against all the variants (except HIV-1APV R, with EC50s of 2.8 to 3.3 nM (differences were 6- to 7-fold greater compared to those against HIV-1NL4-3) (Table 2).

*The amino acid substitutions identified in the protease-encoding region compared to the wild-type HIV-1_LTR include the following: M46I, V82F, and I84V in HIV-1_RTV; L10I, I15V, E34Q, K43I, M46I, V82F, and Q92K in HIV-1_LTR; L10I, K20R, L24I, M36I, M46L, I50V, V82A, and L90M in HIV-1_ATV; and L10I, V32I, M46I, I50V, A71V, and I84V in HIV-1_APV.

Antiviral activities of GRL-0519 and -0529 against laboratory PI-resistant HIV-1 variants

GRL-0519 exerts potent activity against highly PI-resistant clinical HIV-1 isolates. In our previous work, we isolated highly multi-PI-resistant primary HIV-1 strains, HIV-1_HIV-1, HIV-1_HIV-1, HIV-1_HIV-1, HIV-1_HIV-1, HIV-1_HIV-1, and HIV-1_HIV-1, from patients with AIDS who had failed then-existing anti-HIV regimens after receiving 9 to 11 anti-HIV-1 drugs over 32 to 83 months (19, 20). These primary strains contained 9 to 14 amino acid substitutions in the protease-encoding region, which have reportedly been associated with HIV-1 resistance against various PIs (Table 3, note a). The potency of APV, ATV, and LPV against such clinical multidrug-resistant HIV-1 strains was significantly compromised, as examined in PHA-PBM as target cells using p24 production inhibition as an endpoint (Table 3). However, GRL-0519 exerted potent antiviral activity, and its EC_{50} for these clinical variants were quite low: 0.8 to 3.4 nM (Table 3). The antiviral activity of GRL-0519 proved to be most potent against the six multidrug-resistant clinical HIV-1 variants examined compared to the four FDA-approved PIs (APV, ATV, LPV, and DRV). We also examined the antiviral activity of GRL-0519 against highly DRV-resistant variants (28). These variants were created using the mixture of 8 highly multi-PI-resistant clinical isolates as a starting HIV-1 source and selected with increasing concentrations of DRV. GRL-0519 maintained its activity against highly DRV-resistant MDR mixtures (EC_{50} of 30.0 nM), being more potent than DRV by 7.8- to 8.5-fold (Table 3). Overall, GRL-0519 exerted stronger antiviral activity against various wild-type HIV-1 strains, drug-resistant variants, and HIV-2 strains than DRV by 5- to 22-fold. Furthermore, GRL-0519 was more potent than APV by 118- to 925-fold against HIV-2 and drug-resistant variants (Tables 1 and 3).

Effects of human serum proteins on the antiretroviral activity of GRL-0519. The binding of human serum proteins to a
drug is an important determinant of its pharmacological activity in vivo, because overly tight binding may result in reducing interactions between the drug and its target (29). We thus determined the effects of the binding of HSA and AAG on GRL-0519’s antiretroviral activity in vitro. Physiologically normal concentrations of HSA (40 mg/ml) and AAG (10 μM) were used to evaluate their binding effects on GRL-0519’s activity against a wild-type clinical isolate, HIV-1ERS104pre. All four FDA-approved drugs substantially maintained their activity in the presence of HSA, with reduction of activity by up to 5-fold relative to the activity in the absence of additional HSA (Table 4). The activities of those PIs were reduced in the presence of AAG by 7- to 12-fold (Table 4). However, the binding effects of both HSA and AAG on GRL-0519’s activity were insignificant, only a 3- to 4-fold difference. Of note, GRL-0519’s EC50 with HSA or AAG (1.9 to 2.4 nM) significantly exceeded those of the four FDA-approved PIs (Table 4).

* HSA (40 mg/ml) or AAG (10 μM) was used to evaluate the binding effects of human serum proteins on GRL-0519 and -529 antiviral activities. The EC50 values against HIV-1ERS104pre with or without HSA or AAG were determined by p24 assay using PHA-PBM endpoints. The numbers in parentheses represent the fold changes of the EC50 values compared to the values without HSA or AAG. The data shown represent mean values derived from the results of two or three independent experiments. PBMs were derived from a single donor in each independent experiment.

In vitro selection of HIV-1 variants resistant to GRL-0519. We next attempted to select HIV-1 variants resistant to GRL-0519 by propagating a laboratory HIV-1 strain, HIV-1NL4-3, in MT-4 cells in the presence of increasing concentrations of GRL-0519 as previously described (24). HIV-1NL4-3 was initially exposed to 0.0007 μM GRL-0519 and underwent 37 passages, after which the concentration of GRL-0519 was found to have increased 19-fold (0.0131 μM) compared to that at the initiation of selection. Judging from the amounts of p24 Gag protein produced in the culture medium (up to ~282 ng/ml), the replicative capacity of HIV-1NL4-3 at passage 37 (HIV519_37) was thought to have been reasonably well maintained. Compared to the kinetics of the emergence of variants resistant to APV, the emergence of GRL-0519- and DRV-resistant variants was substantially delayed (Fig. 2). Of note, HIV-1 variants resistant to APV and capable of replicating at >5 μM emerged by passage 20, and variants resistant to GRL-0529, replicating at >1 μM, emerged by passage 6, while it became fairly difficult to increase the concentrations of DRV and GRL-0519 around and beyond passage 20, since the virus populations ceased to replicate with further increased concentrations.

The protease-encoding region of the proviral DNA isolated from infected MT-4 cells was cloned and sequenced at passages 6, 13, 22, 29, and 37 under GRL-0519 selection. The sequences of the region cloned and the percent frequency of identical sequences at each passage are depicted in Fig. 3. By passage 13, the wild-type protease gene sequence was seen in 7 of 19 clones, although an N37S substitution was noted in 10 of the 19 clones. However, by passage 22 and beyond, N37S disappeared, and the virus had mostly acquired K43I and A71T substitutions. As the passages proceeded, greater numbers of amino acid substitutions emerged. At passage 29, V82I substitution was seen in 16 of 22 clones, and V82I became dominant by passage 37 (25 of 26 clones). An L3V substitution was also observed in 4 of the 26 clones by passage 37. Reportedly, APV-resistant HIV-1 variants contain V32I, I50V, I54L/M, L76V, I84V, and L90M substitutions (30, 31), and such substitutions were also identified in the present study (data not available).

FIG 2 In vitro selection of PI-resistant HIV-1 variants. HIV-1NL4-3 was propagated in MT-4 cells in the presence of increasing concentrations of amprenavir (●), darunavir (△), GRL-0519 (◆), or GRL-0529 (○). Each passage of virus was conducted in a cell-free manner.
shown). However, no such APV resistance-associated amino acid substitutions emerged during the GRL-0519 selection (Fig. 3). Additionally, HIV-1 selected with GRL-0519 (HIV519R37) acquired the following Gag amino acid substitutions: E17K and V84A in the matrix (MA) region and G61E and D152N in the CA region. HIV519R37 fails to replicate at a low concentration of GRL-0519. Since the replicative capacity of HIV519R37 was thought to be reasonably well maintained despite the presence of GRL-0519, as mentioned above, we determined the replication kinetics of HIV519R37 and HIV-1NL4-3. As shown in Fig. 4A, HIV-1NL4-3 failed to replicate in the presence of as little as 0.005 μM GRL-0519 during the entire culture period of 7 days. However, HIV519R37 was capable of replicating in the presence of 0.005 and 0.01 μM GRL-0519, and the amount of p24 produced in the culture

FIG 3 Amino acid sequences of the protease-encoding regions of HIV-1NL4-3 variants selected in the presence of GRL-0519. The amino acid sequences of protease, deduced from the nucleotide sequence of the protease-encoding region of each proviral DNA isolated at each indicated time, are shown. The amino acid sequence of the wild-type HIV-1NL4-3 protease is illustrated at the top as a reference.

FIG 4 Replication kinetics of HIV-1NL4-3 and HIV519R37. MT-4 cells (3.2 × 10^5) were exposed to a HIV-1NL4-3 or HIV519R37 preparation containing 10 ng/ml p24 in 6-well culture plates for 3 h, and the MT-4 cells were washed with fresh medium and divided into 4 fractions, each cultured with or without GRL-0519 (final concentration of MT-4 cells, 10^4/ml; drug concentrations, 0, 0.005, 0.01, and 0.015 μM). The amount of p24 produced in each culture flask was measured every 2 days for up to 7 days, once at each time point.
medium reached the amount without GRL-0519 by day 7. However, HIV-1 NL4-3 P37 failed to replicate in the presence of 0.015 μM GRL-0519, and no p24 was detected throughout the culture period (Fig. 4B).

**Roles of 3 amino acid substitutions that emerged during selection with GRL-0519 in GRL-0519’s anti-HIV-1 activity.** We also examined the roles of 3 substitutions that emerged during the GRL-0519 selection experiment, K43I, A71T, and V82I, using a p24 assay. The data shown represent mean values (±1 SD) derived from the results of two or four independent experiments. The numbers in parentheses represent the fold changes of EC_{50} compared to the value against HIV-1 NL4-3.

In vitro selection of a mixture of 8 HIV-1 MDR variants resistant to GRL-0519. As described above and as shown in Fig. 2, the emergence of HIV-1 variants resistant to GRL-0519 was much delayed, and it took as many as 37 passages (37 weeks) for the virus to acquire its replicative activity in the presence of low concentrations (~0.01 μM). Thus, we attempted to select out GRL-0519-resistant variants using a mixture of 8 multidrug-resistant clinical isolates (HIV-1 MDR) as a starting HIV-1 population, as previously described (28, 32). We performed an additional selection experiment with MT4 cells and a mixture of 8 HIV-1 MDR variants as a starting virus population, with APV, DRV, and GRL-0519 and -0529. Similar to the results of selection experiments using MT-4 cells and HIV-1 NL4-3, the emergence of HIV-1 strains capable of replicating in the presence of GRL-0519 was significantly delayed compared to the cases with APV and DRV (Fig. 5).

**Structural analyses of GRL-0519 interactions with protease.** We have recently reported the crystal structure depicting the binding mode and interactions of GRL-0519 with protease (17). GRL-0519 has a tris-THF moiety as its P2 ligand, and DRV has a bis-THF group as its P2 ligand (Fig. 1). Another difference is that GRL-0519 has a methoxybenzene as a P2’ ligand, whereas DRV has an aniline. We analyzed the crystal structure of GRL-0519 with protease and compared it with the structure of protease complexed with DRV. We found that the oxygens of the first and second THF rings of GRL-0519 form hydrogen bond interactions with the backbone amide nitrogens of Asp-29 and Asp-30 in the S2 binding pocket of the protease (Fig. 6A). The urethane NH of GRL-0519 forms a hydrogen bond with Gly-27. The hydroxyl group of GRL-0519 forms hydrogen bonds with the catalytic Asp-25 and Asp-25’.

The oxygen of the methoxybenzene (P2’ ligand) of GRL-0519 forms a hydrogen bond with the backbone amide nitrogen of Asp-29 = Asp-29 = THF group as its P2 ligand (Fig. 1). Another difference is that GRL-0519 has an aniline as the P2’ ligand, whereas DRV has a bis-THF ligand, whereas DRV has an aniline. We analyzed the crystal structure of GRL-0519 with protease and compared it with the structure of protease complexed with DRV. We found that the oxygens of the first and second THF rings of GRL-0519 form hydrogen bond interactions with the backbone amide nitrogens of Asp-29 and Asp-30 in the S2 binding pocket of the protease (Fig. 6A). The urethane NH of GRL-0519 forms a hydrogen bond with Gly-27. The hydroxyl group of GRL-0519 forms hydrogen bonds with the catalytic Asp-25 and Asp-25’.

The oxygen of the methoxybenzene (P2’ ligand) of GRL-0519 forms a hydrogen bond with the backbone amide nitrogen of Asp-29 = Asp-29 = THF group as its P2 ligand, whereas DRV has a bis-THF ligand, whereas DRV has an aniline. We analyzed the crystal structure of GRL-0519 with protease and compared it with the structure of protease complexed with DRV. We found that the oxygens of the first and second THF rings of GRL-0519 form hydrogen bond interactions with the backbone amide nitrogens of Asp-29 and Asp-30 in the S2 binding pocket of the protease (Fig. 6A).
for an extra THF moiety to make additional contacts with protease. The crystal structure examined in the present study confirms that the tris-THF moiety fully occupies the binding cavity and forms better van der Waals contacts with protease than the bis-THF of DRV (Fig. 7C and D). Contact (C) is defined by the following formula: 

$$C = D_{12}/(R_1 + R_2),$$

where $D_{12}$ is the distance between atoms 1 and 2 and $R_1$ and $R_2$ are the van der Waals radii of atoms 1 and 2. A good contact is defined as follows: $1.30 > C > 0.89$.

**The tris-THF moiety increases water-mediated polar interactions with protease.** We further analyzed the polar interactions around the tris-THF ring of GRL-0519. The crystal structure shows that there are several water molecules that form polar interactions with GRL-0519 and bridge polar interactions with protease (Fig. 6C). Three water molecules, Wat-1, Wat-2, and Wat-3, form a tight network of hydrogen bonds among themselves and mediate polar interactions between GRL-0519 and the active-site residues. Wat-1 directly bridges the polar interactions between the oxygen of the second THF of GRL-0519 and Asp-29. The oxymethyl oxygen of the third THF ring of GRL-0519 enhances the strength of these networks of hydrogen bonds by its polar interactions with Wat-3 and Wat-4 (Fig. 6C). Wat-2 and Wat-3 also bridge the polar interaction between the oxymethyl of the third THF and Arg-87. There is one polar interaction between the third oxymethyl and Arg-8’ through Wat-3 and another network of polar interactions through Wat-4, Wat-5, and Wat-6. The crystal structure of DRV indicates the presence of five water molecules in this region compared to six present for GRL-0519 (Fig. 6D). The tris-THF of GRL-0519 and the additional water molecule are responsible for forming a total of 18 hydrogen bonds in this region compared to 14 for DRV, which has a bis-THF group as its P2 ligand.

**DISCUSSION**

GRL-0519, which contains a unique cyclic ether-derived nonpeptide P2 ligand, tris-THF, and a sulfonamide isostere, suppressed the replication of a wide spectrum of wild-type HIV-1 and HIV-2 strains with extremely low EC$_{50}$s (Table 1). GRL-0519 was highly potent against a variety of multidrug-resistant clinical HIV-1 isolates with EC$_{50}$s ranging from 0.0008 to 0.0034 μM, while the existing FDA-approved PIs examined either failed to suppress the replication of those isolates or required much higher concentrations for viral inhibition (Table 3). GRL-0519 also efficiently blocked, with an EC$_{50}$ of 0.03 μM, the replication of a highly DRV-resistant variant (HIVDRV)$_{R_{P20}}$, to which the three PIs (APV, ATV, and LPV) had EC$_{50}$s of >1 μM and DRV had an EC$_{50}$ of 0.255 μM (Table 3). Moreover, GRL-0519 exerted potent activity...
against laboratory PI-selected HIV-1 variants (except HIV-1<sub>APV</sub> R<sub>5</sub>/H9262 M) with significantly low EC<sub>50</sub>s (Table 2). GRL-0519 was less potent against HIV-1<sub>APV</sub> R<sub>5</sub>/H9262 M, with an EC<sub>50</sub> of 38.0 nM (a 76-fold difference), presumably due to the structural resemblance between GRL-0519 and APV, both of which contain a sulfonamide isostere (Fig. 1).

In an attempt to explain why GRL-0519 showed such potent activity against both wild-type and drug-resistant variants, we analyzed the crystal structure of the protease–GRL-0519 complex with protease (PDB ID, 3OK9). GRL-0519 has strong polar interactions with multiple regions of protease (Fig. 6A and C). The oxygens from two of the THF rings of GRL-0519 have strong polar interactions with the backbone amide nitrogens of Asp-29 and Asp-30. GRL-0519 also forms hydrogen bonds with Gly-27 and with the side chains of the catalytic aspartates, Asp-25 and Asp-25'. The sulfonamide oxygen and the carbonyl oxygen form polar contacts with Ile-50 and Ile-50' in the flap through the bridging water molecule. Comparison of the crystal structures of protease complexes with GRL-0519 and protease complexes with DRV highlights the similarities and differences in interactions between these two inhibitors. The two oxygens from the bis-THF of DRV form hydrogen bond interactions with the backbone amide nitrogens of Asp-29 and Asp-30 (Fig. 6B). DRV also forms polar interactions with Gly-27, Asp-25, and Asp-25' and polar contacts with the protease flap through the bridging water molecule. However, there are important differences in the interactions of GRL-0519 and DRV with protease. An additional water molecule (Wat-3 in Fig. 6C) around the tris-THF ring of GRL-0519 is observed in the crystal structure. This water molecule forms hydrogen bond interactions with the third THF ring of GRL-0519 and enhances the polar contact through a network of hydrogen bonds with Asp-29, Thr-26, Arg-87, and Arg-8'. There are four additional polar contacts arising out of the presence of the third THF ring of GRL-0519 and Wat-3 compared to the water-mediated polar interactions in this region of the protease complexes with DRV (Fig. 6D). Even though both GRL-0519 and DRV form polar interactions with the backbone atoms of Asp-30' in the S2 site, they interact with different sets of atoms (Fig. 6A and B). GRL-0519 forms the hydrogen bond with the amide nitrogen, whereas DRV forms polar contact with the carbonyl oxygen of Asp30'. The van der Waals surface interactions of GRL-0519 and DRV are also different (Fig. 7A to D). The tris-THF and methoxy group of GRL-0519 form

**FIG 7** van der Waals interactions of GRL-0519 and darunavir with protease. GRL-0519 is shown as sticks (green carbons), and the van der Waals surfaces of selected moieties of GRL-0519 and its complexed protease are shown in gray and blue, respectively. DRV is shown as sticks (gray carbons), and the van der Waals surfaces of selected moieties of DRV and its complexed protease are shown in yellow and plum, respectively. (A and B) van der Waals interactions between the benzomethoxy of GRL-0519 and Asp-29' and Asp-30' of protease (A) and interactions between the aniline of DRV and Asp-29' and Asp-30' of protease (B). The surface interactions suggest that the methoxy group of GRL-0519 makes stronger van der Waals interactions with Asp-29' and Asp-30' of protease than does DRV. (C and D) The molecules are rotated to show the van der Waals surface interactions of the tris-THF (C) and bis-THF (D) moieties with protease. The tris-THF group of GRL-0519 forms better van der Waals contacts at the S2 site of protease than the bis-THF of DRV. The figures were made with Maestro version 9.3 (Schrödinger, LLC, New York, NY, 2012).
stronger van der Waals contacts with the S2 and S2’ sites of protease, respectively. These interactions are stronger than the corresponding interactions of the bis-THF and aniline groups of DRV.

It should be noted that GRL-0519, as previously reported (35), blocks the dimerization of HIV-1 protease monomer subunits more potently, by at least 10-fold, than DRV, as examined by a fluorescence resonance energy transfer (FRET)-based HIV-1 expression assay that uses cyan (CFP) and yellow (YFP) fluorescent protein-tagged protease monomers (17). Considering that the dimerization of HIV-1 protease subunits is an essential process for its acquisition of proteolytic activity, which plays a critical role in the maturation and replication of the virus (36), the potent activity of GRL-0519 to block protease dimerization should also contribute to the greater antiviral potency of GRL-0519 than of DRV. Taken together, the stronger polar and nonpolar contacts of GRL-0519 with protease, as observed in its crystal structure, in its presence to its potential act to block protease dimerization, are likely to be responsible for its much more potent antiviral activity than that of DRV.

In our study, all the PIs examined showed no significant reduction of antiviral activity with the addition of HSA (Table 4). In contrast, the addition of AAG substantially reduced the antiretroviral activities of APV, ATV, and DRV by more than 9-fold, and their EC_{50} increased to 286.3, 32.7, and 33.8 nM, respectively. However, the reduction with GRL-0519 was only 4-fold, and its absolute EC_{50} was as low as 2.4 nM (Table 4). AAG is an acute-phase protein, and its concentration can increase upon injury, surgery, inflammation, malignancy, and infection, including HIV-1 infection (29, 37). Therefore, this feature of GRL-0519 may represent an advantage for its potential clinical application.

In our HIV-1_{NL4-3} selection experiment using GRL-0519, the emergence of GRL-0519-resistant variants was substantially delayed compared to other PIs and DRV. The use of a mixture of multiple-drug-resistant HIV-1 isolates can expedite the emergence of variants resistant to the drug used for the selection in vitro through homologous recombination and should reflect what occurs within individuals harboring a number of drug-resistant HIV-1 species (quasispecies) (28, 32). Thus, in this study, we also employed the mixture of 8 different multi-PI-resistant clinical isolates as a starting viral population (Fig. 5). In the present study, by passage 37, 3 major amino acid substitutions (K43I, A71T, and V82I) were identified in PR of HIV-1_{NL4-3}. The residue V82 is located in the vicinity of the binding pocket of the protease and forms van der Waals contact with GRL0519. The V82A substitution is reported to be associated with resistance against various protease inhibitors (33, 34). However, K43 and A71 are distal from the inhibitor binding pocket and have no direct association with GRL0519. Thus, it is likely K43l and A71T are secondary substitutions. It is particularly noteworthy that we failed to select the A28S amino acid substitution in the present selection experiment with GRL-0519. In our previous studies of potent PIs, such as TMC-126 and GRL-1398, containing a paramethoxy group in the P2’ site, the A28S amino acid substitution was identified as a resistant variant (19, 25). In this regard, the combination of tris-THF as the P2 ligand and the paramethoxy moiety at P2’ seems to have prevented the selection of the A28S substitution as a resistant variant.

The tris-THF moiety has more interactions with the S2 site of the protease than the bis-THF present in either TMC-126 or DRV. Also, the p-OCH3 moiety seems to have more favorable van
